

# Galvanize Memory

---

You're making an API that can list, create, read, update, and delete a collection of coffee. The problem is that you're missing a critical part of the API-- the database! Create a database for this API, and interface with it via [Knex.js](#).

## Setup

Make a local database and setup a `knexfile` to connect to it.

## Migrate

Make a migration that creates the following database table:

`coffee`

| key | name    | data type                 |
|-----|---------|---------------------------|
| PK  | id      | auto-incrementing integer |
|     | name    | text                      |
|     | roaster | text                      |
|     | aroma   | integer                   |

## Seed

Seed your database with some data:

| field   | value         |
|---------|---------------|
| id      | 1             |
| name    | Black and Tan |
| roaster | Ink           |
| aroma   | 3             |

|  |  |
|--|--|
|  |  |
|--|--|

| field   | value         |
|---------|---------------|
| id      | 2             |
| name    | Holiday Roast |
| roaster | Starbucks     |
| aroma   | 9             |

| field   | value         |
|---------|---------------|
| id      | 3             |
| name    | House Quake   |
| roaster | Denver Coffee |
| aroma   | 6             |

Make sure your next auto-incrementing integer starts with 4 !

## Database connection

Make a connection to your database in the `database-connection.js` file with the appropriate environment data.

## Queries

Fill out the `queries.js` file with the following:

- `list()` should return a promise that resolves with all of the data in the `coffee` table as an array
- `read(id)` should return a promise that resolves with the record with a matching `id` as an object
- `create(coffee)` should return a promise that inserts a coffee object and resolves to the created database record as an object
- `update(id, coffee)` should return a promise that updates a coffee record matching `id` with the data in `coffee` and resolves to the updated database record as an object
- `delete(id)` should return a promise that removes the record matching `id` and resolves to nothing

## Deployment

Deploy this API. Note that you'll need to create a remote database, run your migration and seeds on it, and connect to it in production and your local database in development.

## Notes

- You can test your API locally with `npm test`

Add a link to your [deployed API]() here.
